

Install a Perl Module

(WHM >> Home >> Software >> Install a Perl Module)

- Overview
- Perl Module Magic User Loader
- Perl Module Installer
- Installed Perl Module(s)
- Additional documentation

Overview

A Perl module is software in the Perl programming language. Often, you may use Perl modules in scripts. To properly integrate a Perl module into a script, retrieve the module from a central repository and install it on your server.

Note:

This interface installs Perl modules to the system's Perl installation. For more information, read our [Guide to Perl in cPanel & WHM documentation](#).

Perl Module Magic User Loader

Warning:

As of cPanel & WHM version 11.36, this feature is **deprecated**. If you disable this feature, you **cannot** reenabte it.

This feature allows users to integrate Perl modules into scripts without the need to specify a separate path to the installed modules.

Perl Module Installer

The *Perl Module Installer* feature allows you to search for, download, and install a Perl module from the [CPAN repository](#).

Note:

If you know the exact name of the module that you wish to install, enter its name in the *Install a Perl Module* text box and click *Install Now*.

To search for and install a Perl module, perform the following steps:

1. Use one of the following methods to find the desired module:
 - Enter a search term in the available text box and click *Go*.
 - Click *Show Available Modules* to list CPAN-provided Perl modules.
2. The interface displays the following information for all of the displayed modules:
 - *Module Name* — The module's name and version number.
 - *Description* — A description of the module.
 - *Actions* — The actions that you may perform for that module.
3. Click *Install* next to the module that you wish to download and install.
 - To view a module's documentation, click *Show Docs* for that module.
 - If you did not find the desired module, enter a new keyword in the *Search* text box and click *Go*.

Installed Perl Module(s)

The *Installed Perl Module(s)* table lists all of the modules that exist on your server.

For each installed module, the table displays the following information:

Column	Description
<i>Module Name</i>	The module's name.

Actions

You can perform the following actions for each module:

- *Update* — Update the module.
- *Reinstall* — Reinstall the module from CPAN.
- *Uninstall* — Remove the module from your server.
- *Show Docs* — Read the module's documentation on CPAN.
